Data Center Switch to Aggregation Cabinet

Overview

Data Center Multi-Tier Model Design The data center core layer provides a fabric for high-speed packet switching between multiple aggregation modules. This.

Key Takeaways

In a data center, access switches connect to aggregation switches to consolidate traffic and provide high-speed, scalable connectivity to the core network. Role of the Aggregation LayerThe aggregation layer serves as the intermediate layer between access switches and the core network, consolidating traffic from multiple access switches, wireless access points, or other edge devices before forwarding it to the core switches or routers. It provides Layer 2 and Layer 3 services, including routing, VLAN termination, load balancing, firewalling, and SSL offloading.

Aggregation switches also support link aggregation protocols like LACP to combine multiple physical links into a single logical connection, enhancing bandwidth and redundancy.

Connecting Access Switches to Aggregation Switches

When connecting a data center switch (access layer) to an aggregation cabinet: Use high-speed uplinks (typically 10 GigE or higher) to handle the aggregated traffic. Implement redundancy by dual-homing access switches to multiple aggregation switches, often using virtual port channels (vPCs) to allow Layer 2 multipathing and failover. Maintain Layer 2 adjacency at the access layer while performing Layer 3 routing at the aggregation layer to optimize broadcast domains and support high availability.

Consider VLA

N and subnet design, with Layer 3 interfaces (SVIs) on the aggregation switches providing gateway redundancy using protocols like HSRP.

Scaling and Redundancy

Aggregation switches are often deployed in pairs or modules to scale connectivity as more servers are added. Redundant aggregation modules ensure high availability and allow the data center to handle large numbers of sessions efficiently. Services such as firewalls, load balancers, and intrusion detection are typically integrated at the aggregation layer to offload processing from the core.

Best Practices

Use Layer 2 at the access layer and Layer 3 at the aggregation layer to simplify high availability features like NIC teaming and VMware HA. Test CEF-based load balancing and Layer 3 plus Layer 4 hashing algorithms to optimize traffic distribution across aggregation links.

Ensure SA

N connectivity is considered if storage traffic is present, using Fibre Channel or Ethernet for IP storage. By following these guidelines, connecting a data center switch to an aggregation cabinet ensures efficient traffic consolidation, high availability, and scalable network performance.
