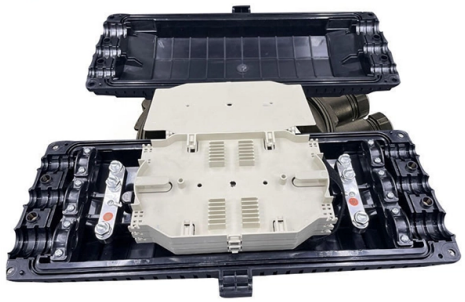
Optical Power Repeater Amplifier



Overview

Optical amplifiers are best suited for shorter transmission distances between the transmitter and receiver. An optical repeater receives the optical signal and converts it into an electrical signal. Such repeaters are used to extend the reach of optical communications links by overcoming loss due to attenuation of the optical fiber. As the amplified, distorted signal continues its journey, the noise component also gets further distorted, potentially compounding. With a capacity of 40,000 simultaneous phone calls on just two pairs of single-mode glass fibers (with one pair in reserve), TAT-8 bested the most advanced coaxial transatlantic cables by a factor of ten. The PON extender can provide 3R (i. re-amplification, reshaping and retiming) regeneration to signals during optical transmission, amplify weak input of optical.
