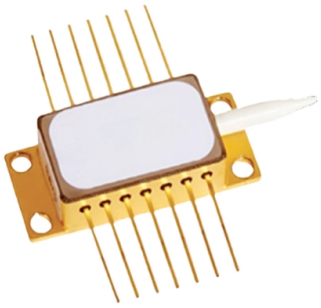
New Materials for High-Speed Optical Modules



Overview

Silicon photonics for high-speed communications and photonic signal. We describe how silicon photonic circuits can be used to perform unitary matrix oper.

Key Takeaways

High-speed optical modules rely on advanced semiconductors like InP, GaAs, and Si, along with novel PCB laminates, 2D materials, and heterogeneous integration to achieve ultrafast data rates and energy efficiency.

Semiconductor Materials

Indium Phosphide (InP) is widely used for high-speed lasers and photodetectors due to its high electron mobility, enabling fast modulation rates and low signal distortion, and its ability to emit at 1550 nm, ideal for long-haul fiber-optic communication. Gallium Arsenide (GaAs) is commonly used for VCSELs in short-reach applications (850–980 nm) because of its cost-effectiveness and thermal performance. Silicon (Si) is central to silicon photonics, allowing integration of modulators, waveguides, and detectors on a single chip, often combined with III-V materials for hybrid integration.

Emerging materials like 2D materials and topological insulators are being explored for ultra-compact, high-speed photonic devices.

PC

B and Substrate MaterialsHigh-speed optical modules require advanced PCB laminates with low dielectric loss (low Df) and CTE-matched materials to maintain signal integrity and thermal reliability at 400G, 800G, and 1.6T speeds.

Multi-layer HDI PC

Bs with laser microvias and embedded copper blocks are used to reduce crosstalk, skew, and power loss while supporting high-density integration. Materials like M6 laminates and precision finishes are increasingly adopted for 10–16 layer PCBs in next-generation modules. Modulators and Integration MaterialsNext-generation modulators use thin-film lithium niobate or electro-optic materials integrated with silicon photonics, offering >100 GHz bandwidth and low drive voltage (
