Optical module sensitivity specifications

Overview

In optical communication systems, sensitivity is a measure of how weak an input signal can get before the bit-error ratio (BER) exceeds some specified number. The standards body governing the application sets this specified BER. These optical module parameters dictate: Compatibility: Will it work with your switch, router, and cabling?

Performance: What data rate and distance can it achieve?

Reliability: Will it operate stably within your. Receiver sensitivity stands as a critical parameter impacting an optical transceiver's functionality. It denotes a module's capability to function in challenging environments and aids network operators in determining the system's maximum reach or link margin. The units for transmit optical power and receive sensitivity are both dBm. Generally, the higher the rate, the poorer the receive sensitivity, meaning a larger. This article will systematically analyze the core performance indicators of optical modules from five dimensions: transmit optical power, receive optical power, overload optical power, receiver sensitivity, and extinction ratio.
