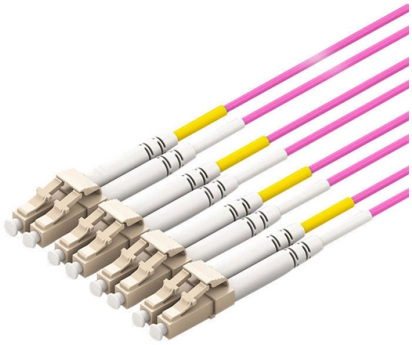
Why do 100G optical modules use wavelength division multiplexing



Overview

Both utilize wavelength division multiplexing technology to combine multiple optical signals of different wavelengths onto a single optical fiber, thereby increasing fiber capacity and transmission distance. This technique enables bidirectional communications over a. Based on differences in wavelength spacing and system complexity, optical modules are mainly divided into two major technological paths: coarse wavelength division multiplexing (CWDM) and dense wavelength division multiplexing (DWDM). Multi-wavelength optical modules mainly categorize into CWDM and. CWDM4 is a 100G optical transceiver standard defined by the CWDM4 MSA (Multi-Source Agreement) group, designed to meet data centers' needs for medium-distance, compact and cost-controlled optical interconnects. A modulation scheme continuously alters the property or properties of a waveform.
